Sub-surface drilling techniques for producing oil and natural gas typically involve "directional" drilling and the use of various drill string components such as stabilizers, drill collars, measurement and monitoring equipment, reamers, choke and kill mechanisms, stabilizers, casing strings, and various other drilling components. Successful directional drilling involves the ability to drill a hole along a desired path that remains on a desired target path. Sometimes drilling can result in the drill string becoming stuck in the hole. Such a situation can occur, for example, when a portion of the drill string becomes stuck against an existing casing string or in a low-permeability formation. Such a phenomenon results in a "hole-stuck" state. The result is that the drilling process must be suspended, and some form of relief must be provided. Typically, a "spacer" or a "window" is formed in the casing by milled slots or holes at the desired depth and azimuth of the hole to be drilled so that the drill string can be removed from the hole and drilling can begin again. The process of milling a hole into the casing string is time consuming and expensive. Furthermore, once formed, the aperture in the casing typically cannot be closed or sealed to prevent unintended leakage of fluids into or out of the well. While certain attempts have been made to provide a casing that can be installed in a sub-surface wellbore and subsequently sealed, such as shown in U.S. Pat. Nos. 6,119,373, 6,119,373, 6,318,971, 7,257,463 and 6,941,401, there remains a need for improved techniques and systems for sealing casing at pre-selected depths in

a sub-surface
